ENERGY DATABASE

Energy Database is a computerised bibliographical information system that runs on an IBM Compatible personal computer. The database has been created using the software package 'Scimate' developed by the Institute of Scientific Information, ISI, USA. The present document is a partial output of the database and it provides reference to over 200 articles selected from latest energy publications. Those who wish to have copies of the original document are requested to make use of our regular photocopy service (please see the prescribed order form).

It is proposed that the data base, if possible, should also be made available in standard 5 1/4" floppies. The users should have an IBM or compatible personal computer and also the scimate software. For further information please write to:

01 COAL AND COAL PRODUCTS

001 Alcohols and Coal-based Liquid Fuels for Automotive and Stationary Diesel Engines.

Deals with the research in progress at the University of Trieste on the use of alternative fuels in Diesel engines. Tests have been made on methanol and ethanol among alcohols, SRC-II and COED among coal-based liquid fuels; their main characteristics, particularly the possibility to increase inflammability, have been carefully taken under examination. The influence of these fuels on performances of various types of engines has been evaluated in comparison with diesel fuel standard operation.

Giadrossi, Alessandro

Int. J. Energy Systems 5,2;1985;76-81(6p)

002 Developing Coal in Developing Countries.

A number of developing countries have substantial coal reserves but have had difficulties with restructuring energy consumption patterns, transportation and supply bottlenecks. Consequently these governments have allowed multinational corporations to exploit their reserves for export. The host countries must have a detailed understanding of cost and revenue sharing arrangements. Environmental, social and health impacts may effectively externalize costs and must be taken into consideration when planning for the development of coal reserves.

Chadwick, Michael and others

Ambio 14,4-5;1985;249-252(4p)

003 Returns to Scale in U.S. Surface Mining of Coal

A parametric class of ray homothetic production functions that can be estimated with the ordinary least squares method has been introduced in order to study returns to scale and optimal scale in U.S. surface mining of coal. For each of the state-wide representative mines, both the returns to scale and optimal output level corresponding to its current output mix has been calculated, based on the estimated production function.

Resources and Energy 7,4; December 1985; 341-352 (12p)

004 Some Considerations of Start Up in the Design of Fluidized Bed Boilers.

Describes an auxiliary start-up system as required in fluidized bed combustors in order to heat the bed to a temperature at which coal fed to the bed will ignite and burn without producing excessive smoke. To illustrate the nature of the design calculations associated with start-up, the paper describes the principles of a mathematical model developed to determine the rating of burner required for the hot gas start-up, approach.

02 PETROLEUM

006 Changing Pattern of Third-World Oil Supplies.

The changing pattern of the OICD's oil supplies has closely paralleled the transformation of the structure of the international oil market. The semi-industrial OICD's have gained an entry into the oil market, enabling them to assume an active role in securing their oil requirements directly, without the mediation of major oil companies. Information on OICD's oil imports and the changes in them are obtained from IEDC's Tanker Tracking Information System. A number of tables and graphs concerning the volume and origin of oil imports of some major OICDs are included in this paper.

Karbassioun, Bahman

OPEC Review 9, 3; Autumn 1985; 267-285(19p).

**007 Is the Spot Market for Oil Products Efficient? : Some Rotterdam
Evidence**

This paper presents evidence relating to the efficiency of the Rotterdam market for oil products. Analysis of daily, weekly and monthly price changes for gas oil during the period 1978-83 results in the rejection of the efficiency hypothesis, i.e., relative price changes have been serially dependent. On the basis of this observation, a very simple trading rule is developed. This rule is tested out, simulating market transactions during the first two quarters of 1984. The financial outcome of this game turns out to be rewarding

008 HYDROGEN

009 Characteristics of Hydrogen-Fueled Gas Turbine Cycle with Intercooler, Hydrogen Turbine and Hydrogen Heater.

The performance of a hydrogen fueled gas turbine cycle equipped with an intercooler, regenerator, hydrogen turbine and recuperative hydrogen heater are analyzed. The intercooler is very effective to prevent the condensation and freezing of water vapor in cooling the suction air. The operation of hydrogen turbine in low-temperature range can also be prevented by adopting hydrogen heater. Thermodynamic analysis has revealed that the thermal efficiency and the specific output are considerably improved compared to those of the simple gas turbine cycle.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July, 1984, edited by T.N. Ueziroglu and J.B. Taylor, New York, Pergamon Press, 1984,v3,1303-1307(5p)

011 Coated Silica Shells: An Advanced Hydrogen Storage System.

Preliminary investigation of a new concept which consists of storing hydrogen on a bed of small metal-coated spherical shells of nearly pure silica composition. The silica shells function primarily as high pressure containers, which because of silica's high strength, can withstand the pressures required to achieve significant storage densities. Since pure silica is too permeable to adequately retain hydrogen, a metal (eg.Ni,Cu,Mo) coating is added as a room temperature permeation barrier. The rate at which hydrogen permeates these metals varies rapidly with temperature. Consequently, to cause the hydrogen to readily permeate the metal coating as well as the Silica Shell

requires heating the bed to only moderate temperatures.

12 Energy Conversion Process with Coal and Sulphuric Acid.

In this process, the coal reacts with an oxygen containing substance such as sulphuric acid or metal oxides. Subsequently, this substance is reoxidised with oxygen. The products of the two step combustion process are hydrogen and electric power which are generated by expanding the gaseous products of the high pressure combustion in a gas turbine.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by T.N. Veziroglu and J.B. Taylor, New York, Pergamon Press, 1984, v3, 1135-1143(9p)

13 Hydrogen Absorption - Desorption Characteristics of Zr (Fe(x)Cr(1-x))(2).

A number of potential hydrogen compounds, namely Zr(Fe(x)Cr(1-x))(2)) have been investigated. All alloys studied are predominantly hexagonal Laves phases, with lattice parameters decreasing as 'x' increases. An additional, unidentified phase is observed, increasing in quantity as chromium levels increase. These pseudobinaries absorb hydrogen readily without prior activation, with the exception of Zr (Fe(0.25)Cr(0.75))(2) which is believed to have been poisoned by oxygen occlusion during alloy preparation. P-C-T curves have been measured and thermodynamic quantities determined for Zr(Fe(0.75)Cr(0.25))(2) - H(2) and Zr(Fe(0.70)Cr(0.30))(2) - H(2) systems.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by TN Veziroglu and J B Taylor, New York, Pergamon Press, 1984, v3, 1329-1337(11p)

015 Hydrogen Production by Solar Thermolysis of Water.

Hydrogen production by water thermolysis using solar energy is studied for reactor temperatures of 1500-2500K and pressures of 50-1000 KPa. Separation of hydrogen from the product gases is affected at low temperature via a diffusion-membrane process. Results of simulation and optimisation of a process with a hydrogen production capacity of about 600 GJ per year are presented. Processes with reactors operating at high temperatures and low pressures proved to be thermodynamically more efficient and also more possible with regard to solar energy utilization.

016 Hydrogen Solubility in Mg(2) Ni.

Magnesium nickel hydride is a promising candidate for hydrogen storage. The authors report the hydrogen solubility in Mg(2) Ni and lattice parameter change by hydrogen solubility at 300 C, 355 C and 400 C. From these data the unit cell size change vs hydrogen content and thermodynamic values of solution have been obtained.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by T.N. Veziroglu and J.B. Taylor, New York, Pergamon Press, 1984, v3, 1405-1413 (9p)

017 Photocatalytic Decomposition of Methanol on fine Nickel and Cobalt particle

Photocatalytic decomposition of methanol was studied over titanium di-oxide-supported nickel and cobalt catalysts, varying the sizes of metal particles from 100 to 300 Å for nickel and from 50 to 500 Å for cobalt, respectively. The rate of methanol decomposition was estimated from that of hydrogen evolution and the highest rate was observed when the particle sizes of nickel and cobalt were 170 and 100 Å, respectively. In the present work, titanium tetra-iso-propoxide and the metal nitrates dissolved in ethylene glycol were used to control the metal particles in an even size level, measured by transmission electron microscopy.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto,15-20 July 1984, edited by T.N. Veziroglu and J.B. Taylor, New York, Pergamon Press, 1984,v3,1201-1211 (11p)

020 Solar Photolysis of Water - How Efficient and how Economic?

A summary analysis of the thermodynamic limits on the conversion efficiency of solar water photolysis schemes is presented. It is shown that dual photosystem schemes have a decided advantage over single photosystem schemes. Even when several non-ideal factors are considered, the dual system seems possible to achieve over 15% efficiency as opposed to 10% for single photosystem schemes. Finally, some fundamental concepts are presented which should be considered in any economic analysis of solar water photolysis systems.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984 edited by T N Veziroglu and J B Taylor, New York, Pergamon Press, 1984,v3,949-955(7p)

021 Solar Reactor for High-Temperature Gas Phase Reactions (Water and Carbon Dioxide Thermolysis and Nitric Oxide Synthesis)

This paper deals with an original way for carrying out highly endothermic reactions at high temperature under concentrated radiant energy. Three examples of chemical reactions were chosen : thermal direct decompositions of water and of carbon-dioxide and synthesis of nitric oxide from air. An experimental study consisting of a "dissociation reactor" located at the focus of either an image furnace or a solar concentrator, and a quenching device in which the hot gases are quickly cooled by mixing with turbulent gas jets is described.

Solar Energy 35,2;1985;153-166(14p)

022 Solar Thermochemical Hydrogen: The Heat Source-Process Interface.

A discussion of issues and considerations related to the interface between a solar heat source and a thermochemical hydrogen process and some details of a tubular heat exchanger operating as such include the temperature-heat input requirements for the endothermic reaction, type of receiver, heat storage, transient operations, and control. A thermal performance analysis of a tubular reactor/heat exchanger operating in a cavity type solar receiver is applied to SO_2 decomposition. The analysis produces axial distributions of temperature - tube wall and process fluid, reaction rate, conversion, velocity, density, pressure and residence time.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by TN Veziroglu and J B Taylor, New York, Pergamon Press, 1984, v3, 1101-1109 (9p)

023 Solar Thermochemical Process. Interface Study.

Many thermochemical or thermochemical/ electrochemical hybrid hydrogen production processes involve a step of high temperature decomposition of sulfuric acid. Three cases of coupling the sulfuric acid vaporization and decomposition processes to a solar heat source have been studied. A separate case which uses helium as a heat transport medium to decouple the acid decomposition from the solar heat source is also included for comparison. The process flowsheet and state points for each case are presented. The conceptual design and sizing for the receiver/reactor are included. The fabrication methods for the silicon carbide components are also discussed.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by T.N. Veziroglu and J.B. Taylor, New York, Pergamon Press, 1984, v3, 1123-1133 (11p)

024 Splitting Water with Semiconducting Photoelectrodes - Efficiency Considerations.

An efficiency analysis of photoelectrolysis solar-cells is presented which takes into account fundamental thermodynamic energy losses, as well as all major losses associated with charge transport in semiconductor photoelectrochemical cells (PEC's). A one-photon PEC is found to have an "upper limit" efficiency of 7% (AM 1.2 solar energy to chemical potential energy stored as H_2). For two-photon configurations the "upper limit" for a p-n PEC is 10% while for a tandem PEC it is 18%.

Hydrogen Energy Progress V: Proceedings of 5th World Hydrogen Energy Conference, Toronto, 15-20 July 1984, edited by T.N. Veziroglu and J.B. Taylor, New York, Pergamon Press, 1984, v3, 957-968 (12p)

025 Biogas : will it ever take off?

The potential of biogas to alleviate pressing problems in developing countries, especially regarding small-scale rural applications. The current problems and bottle-necks preventing this technology reaching its maximum potential and the strategies necessary in order to mitigate these problems are the topics of discussion.

Stuckey, David D.

Appropriate Technology 12,2; September 1985;27-29(3p)

026 Biomass Gasifiers for Energy Supply to Agriculture and Small Industry.

Biomass gasifiers may be an important energy alternative for agriculture and small industry in developing countries. They will be more economical than diesel only where the annual operating times are long and the load factor high, unless diesel fuel is very costly. Biomass gasification can be important where the use of small engines to provide mechanical or electrical energy is not economically feasible because of high transportation costs for petroleum fuels or a shortage of foreign currency. Local manufacturing is the most reasonable basis for large scale introduction of biomass gasification in developing countries. There are several obstacles to the introduction of gasifiers, but they can be overcome.

Kjellstrom, Bjorn

Ambio 14,4-5;1985;267-274(8p)

027 Biomass Production and Nutrient Accumulation in Seedling and Coppice Hardwood Plantations.

Total biomass and contents of N, P, Ca, Mg and Mn in above ground tree components of five deciduous species were determined in closely spaced (0.9 x 0.6m) 5-year-old plantations of seedling origin and 5-year-old coppice stands regenerated after the seedling harvest. The proportion of total biomass in bole components increased and in crown components decreased in coppice stands as compared to seedling stands. This resulted in relatively more Ca and less N, P, and K in above-ground tree components of the coppice stands.

Biotech Advs . 3,2;1985;209-218 (10p)

029 Biotechnological Applications of Plant Cells in Culture.

For many workers, the most exciting recent advances in the realm of plant cell biotechnology, center on results obtained from experiments concerned with the genetic engineering of plant cells. Various groups of workers have managed to introduce new genetic material into plant cells, using Ti-plasmids (or modified Ti-plasmids) from *Agrobacterium tumefaciens*. This genetic material has been expressed (with varying degrees of efficiency), in each case. Thus the way may possibly becoming clear to produce plant cell cultures or whole plants with entirely new or novel properties.

Other areas in which progress has been made are in the design of media conditions to promote secondary product formation, and in ways of immobilizing plant cells and enzymes to achieve efficient secondary product formation.

031 Ethanol Fuel from Sugarcane in Brazil.

In November 1975 Brazil initiated a program to raise the production of ethanol from sugarcane and increase the use of ethanol as a substitute for gasoline. Although the Brazilian alcohol program stands out as one of the most significant accomplishments, important aspects of the ethanol program are controversial in both Brazil and other countries. This article analyzes some of the controversial issues by reviewing up-to-date primary data and secondary studies available in Brazil. In particular, the issues of "food vs fuel", economics, employment and energetics are addressed. Some important trends, innovative developments and policy issues that are occurring as part of the Brazilian experience with alcohol fuel are also discussed.

Ambio 14,4-5;1985;293-297(5p)

033 Euphorbia lathyris L. as a Potential Crop Plant. An Outline.

The distribution, botany and history of Euphorbia lathyris L., caper spurge or gopher plant has been outlined. Special consideration is given to the chemical evaluation in respect to seed oil and whole-plant extractable. Seed oil content proved to be very high and its fatty acid composition is unique because of the dominating role of oleic acid. Despite its adaptability to arid environments the plants of E. lathyris exhibit more vigour and therefore produce more biomass per hectare when grown under normal agricultural conditions.

040 Mathematical Model for Ethanol Production by Extractive.

Fermentation in a Continuous Stirred Tank Fermentor

The ethanol fermentation has been examined as a model system for end product inhibition and extractive fermentation and a computer model has been developed predicting the productivity enhancement possible with this technique together with other key parameters such as extraction efficiency and residual glucose concentration. The model predicts a total ethanol productivity of 82.6g/Lh if a glucose feed of 750g/L is fermented with a solvent having a distribution coefficient of 0.5 at a solvent dilution rate of 5.0 per hour. This is more than 10 times higher than for a conventional chemostat fermentation of a 250g/L glucose feed.

Appropriate Technology 12,2; September 1985;17-19(3p)

044 Solid-State Ethanol Fermentation by Means of Inert Gas Circulation.

A new method for solid-state ethanol fermentation was experimented for the ethanol production from solid starchy materials, where a packed-bed-type fermentor was used. Ethanol production was set in by a form of parallel fermentation using a respiration-deficient mutant of *Saccharomyces cerevisiae*. Produced ethanol was simultaneously stripped by circulating inert gas and separated in a condenser. The fermentation efficiency was about 80% which was evaluated much higher than those of conventional solid-state fermentations.

045 Thermophilic Anaerobic Digestion of High Strength Wastewaters.

Studies the thermophilic digestion of vinasse as an example of a high-strength wastewater in reactors with a high biomass retention. Investigates the performance of mixed digesters with a high liquid and biomass retention time, and of reactors with a low liquid but a high biomass retention time. Experiments with (semi) continuously fed digesters can provide information about the effluent quality at high liquid and biomass retention times as a function of the influent concentration and the digestion temperature. This information will be indicative for the effluent quality of reactors with a high biomass and a low liquid retention time.

048 Wood-Fuel and Conventional Fuel Demands in the Developing World.

This paper examines some of the factors influencing the evolution of conventional fuel and wood fuel demands in the developing world. It shows that the resource and balance-of-payments constraints against the use of conventional fuels are less than commonly assumed. It examines the dynamics of wood-fuel resource depletion and discusses the problems of estimating the future demand for wood fuel. The need for a disaggregated analysis that takes into account the differences between categories of domestic fuel consumers is emphasized.

051 Capacitance Measurements of $\text{Cu(2)S-Zn(x)Cd(1-x)S}$ Solar Cells.

Zinc diffusion from Zn(x)Cd(1-x)S into Cu(2)S during the topotaxial formation of the layer and heat treatment of $\text{Cu(2)S-Zn(x)Cd(1-x)S}$ solar cells and Cu diffusion from Cu(2)S into Zn(x)Cd(1-x)S during heat treatment of the cells caused a redistribution of the space charge and potential of the heterojunction. The effect of this redistribution and of the density of the interface states on the capacity of the $\text{Cu(2)S-Zn(x)Cd(1-x)S}$ heterojunction was studied. This study shows that the Zn diffusion into Cu(2)S leads to a compensated layer and thus to an enlargement of the band bending in the Cu(2)S side.

052 Costs of Controlling Environmental Emissions from the Manufacture of Silicon Dendritic Web Photovoltaic Cells.

The annual incremental environmental control costs, based on capital recovery over a ten-year plant life are estimated for integrated and disaggregated plant designs respectively. Capital costs ranged from 50-55% (integrated) and 36-48% (disaggregated) of the estimated costs. Total control costs are small in comparison with current production costs for silicon photovoltaic devices (app \$5/Wp) but will be of greater importance at projected production cost of \$0.5/Wp - \$1.0/Wp. These conclusions are specific to the material and process options examined.

053 Crystal Growth of Cadmium Selenide by Fused Salt Electrolysis and its Photoelectrochemical Properties.

The electrodeposition of CdSe crystals has been examined under potentiostatic condition on graphite electrodes in LiCl-KCl melts containing CdCl(2) and Na(2)SeO(3) . Deposits with various morphologies, needle-like, hollow-like, dendritic and columnar crystals, have been obtained by controlling the deposition potential. These as-grown deposits have fairly good photoelectrochemical characteristics and photoelectrochemical cells with a maximum conversion efficiency of 6.1% under white light illumination of 37mW/cm(2) were constructed using a CdSe photoanode.

054 Effect of a Defective BSF layer on Solar Cell Open Circuit Voltage.

A straightforward analysis of special limiting cases has permitted the determination of the range of possible open circuit voltage losses due to a defective BSF layer. An important result of the analysis is the finding that it is possible to have a fully effective BSF (Back Surface field) region, regardless of the spatial distribution of the defective areas, as long as the total defective area is reduced below certain limits. Distributed defects were found to be much more harmful than lumped defects.

057 Incoherent - Light Induced Diffusion of Phosphorus as a Doping Procedure for Low-Cost Silicon Solar Cells..

Diffusion of phosphorus into p-type silicon from spun on phosphoro-silica films has been induced by means of incoherent light from a xero arc-lamp. A suitable process for solar cell preparation appears to be heating for 20s to 1000 C followed by gradual cooling. Doping profiles measured by the Hall effect exhibit a maximum concentration of $2-3 \times 10^{20}$ cm⁻³ at the silicon surface and a junction depth of about 1500 Å. A number of test-cell batches have been prepared from single- as well as polycrystalline material and very favourable and reproducible spectral-response characteristics have been found. In spite of the non-optimized cell design and a rather primitive antireflective coating, AM1 efficiencies upto 12.7% (single-crystal cell) and 8.2% (polycrystalline cell) have been recorded.

058 Model of Silicon Solar Cells for Concentrator Photovoltaic and Photovoltaic/Thermal System Design.

Semi-empirical expressions are presented for open-circuit voltage, short-circuit voltage, fill factor and conversion efficiency of silicon solar cells as explicit functions of optical concentration (C) and temperature (T). In addition similar expressions are given for the solar cell current as a function of C and T and of the operating voltage V, to enable characterization under conditions of nonoptimal power transfer. The agreement of the model with experimental data is shown to be within 10% for all parameters. An example of an application of the model to system design is also presented.

059 Performance of n⁺-p-p₂ Silicon Cells fabricated through masked ion implantation.

Focuses on the performance of back-surface-field (BSF) Silicon solar cells, whose front n⁺-p junctions were obtained by means of masked ion implantation of (31)P⁺ into p₂-wafers. The distinctive feature of these cells is that the (31)P⁺ ion implantation was performed through a thermally grown silicon dioxide mask 100Å - 700Å thick. The expected impurity profiles of the implanted junctions were obtained through a first-order approximation of the implant/anneal processes. The dependence of the electro-optical characteristics of fabricated devices on the implant parameters is emphasized.

Silard, Andrei P

Solar Cells 15,3; November 1985;211-223 (13p)

060 Photoelectrochemical Behaviour of RuS(2) Semiconducting Electrodes.

In this work some properties such as dark current, quantum efficiency for charge carrier generation and band gap value for sintered and monocrystalline RuS(2) photoelectrodes are explored. Estimated band gap values for the sintered electrode are 1.5 eV for the direct transition, 1.8eV for the indirect transition and 2.3eV for the monocrystal. The stability of the electrodes has also been tested. A careful study of the sintered electrode is reported; the shape and time evolution of the photocurrent are examined as a function of solution pH and the onset of the applied potential. The evolution of the potential of the photocurrent peaks is analysed with respect to the solution pH and the sweep. The kinetics of the photocurrent are determined for different potentials of the electrode.

- 067 Stability Criterion for Tunnel Diode Interconnect Junctions in Cascade Solar Cells.

Studies the degradation due to high temperature annealing of the peak current of $p^+ - n^+$ tunnel junctions in GaAs. Such junctions are intended for use as inter-cell ohmic contacts in cascade solar cells. The current degradation is a consequence of the broadening of the tunnel junction space charge caused by dopant diffusion. It is shown that the peak current is correlated with the dopant concentration profile of the linearly-graded junction. To avoid serious degradation of the peak tunnel current, the product of the larger diffusion co-efficient of donor or acceptor and time at high temperature must be less than $1 \times 10^{-12} \text{ cm}^2$ and impurity diffusion length shorter than 10nm. This criterion is also applicable to materials other than GaAs.

- 070 Thin films of Mercury Cadmium Telluride for Solar Cell Applications.

Electroplated CdS/pHg(1-x)Cd(x) Te (MCT) thin -film solar cells with (1-x) <0.2 are evaluated and compared with electroplated CdS/p-CdTe devices. It is shown that the series resistance limitations commonly observed in CdS/p-CdTe devices can be appreciably reduced if p-CdTe is replaced by p-MCT. This is due to the lower resistivities attainable in p-MCT thin films which in turn reduce both bulk and contact resistances. The possibility of bandgap control in MCT makes it an important candidate material for the production of high-efficiency tandem cells.

Photochemical Conversion

- 071 Anodically Oxidized Titanium Films to be used as Electrodes in Photoelectrolysis Solar Cells.

Special titanium dioxide films which proved to be useful photoanodes for energy-harnessing reactions have been prepared by anodic oxidation of titanium plates in unusual conditions (strong alkaline solutions, very high current densities) The films showed n-type semiconducting properties, even before any reduction treatment, in contrast with what occurs to films obtained following conventional preparation techniques. The photoelectrochemical properties of the films have been determined by measuring the current-potential characteristics, the spectral response and the differential capacitance. The results are discussed together with the potentialities of the applied anodization technique, and the further development of the research are outlined.

1 Comfort Limits for Asymmetric Thermal Radiation.

Groups of 32 and 16 subjects of both sexes were exposed in an environmental chamber to radiant asymmetry caused by a cool wall, a warm wall and a cool ceiling. For cool walls, warm walls and cool ceiling, curves have been established showing the percentage of dissatisfied subjects as a function of radiant asymmetry. Radiant asymmetry at a warm wall caused less discomfort than at a cool wall. A cool ceiling caused less discomfort than a warm ceiling. Accepting that 5% of the subjects may feel uncomfortable, a radiant temperature asymmetry of 10 C is allowable at a cool wall, 23 C at a warm wall and 14 C under a cool ceiling.

Solar Energy 35,5;1985;447-455 (9p)

097 Performance of Series Solar-Assisted Heat Pump Systems in TECH House 1.

The system performance factors measured over two heating seasons of 2.42 and 3.16 compare favorably with both standard active solar systems with heat pump systems. The improved performance in the second year is the result of increased insolation rather than the change to ground coupled storage. Conventional heat pumps cannot take advantage of the higher supply temperature to the evaporator because of design limitations. Improvements in heat pump design are possible to give increased performance.

Reid, R.L. and others.

098 Solar and Heat Pump System - Horsens Swimming Bath, Denmark.

Recently at Horsens, a combined solar system and heat pump system has been constructed together with a centralized control and supervision system. The solar system consists of 300m² flat plate solar collectors without cover glass and insulation. The heat pump system consists of two water-to-water heat pumps with a total effect of 70KW. The energy plant has given a saving of 2.8TJ (670 Gcal) from district heating in the first year which allowing for a use of electricity of 187MWh, amounts to a total of 14000 pounds (DKr 195000).

100 Analysis of the Sanyo Evacuated Tube Solar Collector Test Results from the IEA Task III Programme.

Testing of a set of Sanyo STC-CU250 evacuated tubular collectors and subsequent data reduction has shown that large variations in thermal performance characteristics can result among a collector type taken from a production batch. The differences cannot be attributed to climatic variation as was done in previous intercomparisons.

101 Analytical Model for the Integrated Daily Performance of Solar Air Heating Systems.

An Analytical Integrated Daily Performance Model (IDPM) is developed to predict the long term performance of solar air heating systems. The IDPM is compared to simulation using a fully mixed model of storage and a single-phase model of storage. The comparisons show that the IDPM is more accurate than the mixed model and requires considerably less computation time than simulations using the single-phase model. In addition, the IDPM identifies several parameters that are important to system performance but are not

easily identified by non-analytical analysis.

102 Combination of Flat Plate Solar Collectors of Different Performance.

The analytical model presented in this paper makes it possible to obtain the optimum combination of differently performing flat-plate collectors, in order to maximize the economic benefit of liquid heating solar plants at different temperatures and under different operating conditions. The results justify that combined flat-plate collector systems present better techno-economic performance at high temperatures than single systems with single cover collector.

103 Cylindrical Heat Receiver for Thermal Solar Energy Converters.

Theoretical and experimental results of investigating a cylindrical heat receiver with secondary reflectors are presented. The experimental distribution of the incident flux over the heat-sensitive surface of a heat receiver with secondary reflectors is shown graphically. It is evident that at the beginning and end of the wall, there are deviations from the uniform radiant-flux distribution. This is because the conical secondary reflector does not ensure strictly uniform distribution of the incident flux over the heat-sensitive surface of the heat receiver.

104 Design Considerations for Flat-Plate-Photovoltaic/Thermal Collectors.

Based on a computer simulation of flat-plate PV/T collectors that is applicable to a wide range of designs, the present work focusses on air-type collectors employing single crystal silicon PV cells. The results of the simulations; for PV cells covering greater than 65% of the total collector area, a selective absorber actually reduces the thermal efficiency when used with a gridded-back cells. The requirements for the low emissivity coating are an infrared emissivity of less than 0.25 and a solar transmissivity of greater than 0.85. The optimum combination for an air PV/T was found to consist of gridded back PV cells, a non-selective secondary absorber, and a high transmissivity/low-transmissivity cover above the PV cells.

105 Determining the Basic Operational Characteristics of a Solar Thermostat in the Conditions of Full-Scale Tests.

A method of calculating a heat-receiver-heater and the volume of the heat-store is presented, together with the results of full-scale tests of a solar thermostat with stochastic variations of climatic factors. Analysis of the data obtained shows that, despite stochastic changes in climatic factors, the apparatus ensures the maintenance of the specified temperature conditions ($+40^{\circ}\text{C}$) with an accuracy of up to $+3^{\circ}\text{C}$. The energy capacity of the heat stores allowed optimal temperature conditions to be maintained in the absence of solar radiation for 62 hours.

- 110 Instability Associated with the Onset of Motion in a Thermosyphon.

A theoretical method is presented for the study of the onset of motion in a symmetrical natural circulation loop. A one-dimensional model is applied to describe the behaviour of the flow and linear stability analysis is used for the investigation of its stability. The results show there exists a critical modified Rayleigh number, R_c , below which the rest state is stable and any flow perturbation will decay. The same results have been obtained from a steady-state analysis, there is no steady-state solution when $R < R_c$. For a vertical loop composed of two parallel branches heated from below and cooled from above $R_c = 6$.

- 112 Performance Analysis and Load matching for Tracking Cylindrical Parabolic Collectors for Solar Cooling in Arid Zones.

Line concentrating collectors are being used for heating and cooling. They use a small micro-motor to track the sun in its daily east-west cycle. Due to environmental problems in the site the tracking system has failed. Major design modifications are explained to run the system trouble free. The major concern for solar airconditioning systems is mainly after applying serious energy conservation measures and thermal insulation to the building. There is certain threshold value for system operation and below that limit the system should not operate or it will be wasting electrical energy, not saving it.

114 Performance of a Salt-Gradient Solar Pond for Power Production.

An analytical model of the thermal behaviour of salt-gradient solar ponds is presented. The model is used to predict the performance of a solar pond intended for electric power production. The pond dimensions and heat extraction rate are optimized to achieve a high mean value and small amplitude of pond temperature. The upper convective zone is found to have a deleterious effect on pond performance. The optimum depth of the non-convective zone which maximizes the pond yield is presented. It is found that careful selection of the depth of the lower convective zone and of the amplitude and phase lag of the heat extraction rate can lead to a small value of the amplitude of the pond temperature fluctuations.

- 118 Study on the Structural Properties of a-Si(1-x) Sn(x): H Films prepared by rf Sputtering.

The structure of hydrogenated amorphous silicon-tin alloy films has been systematically investigated as a function of substrate temperature Ts. X-ray diffraction, ir absorption and other characterization measurements were performed. It is shown that most of the Sn atoms go into substitutional Si sites at Ts<220 C whereas a large fraction of B-Sn precipitates are formed at Ts >220 C. The hydrogen as an active chemical agent of the deposition process plays an important role in this structural change.

125 Wind-Induced Heat Losses from Solar Collector Arrays on Flat-Roofed Buildings.

This paper presents data for convective heat transfer coefficients on the front surface of a free-standing array of solar collectors mounted on the flat roof of a low warehouse-type building and exposed to the wind. The data were obtained by testing a 1:36 scale model in highly turbulent nonuniform flows which simulated the natural wind. For typical full scale conditions, the heat transfer coefficients are substantially lower than those given by a commonly used correlation. The coefficients are only mildly sensitive to wind direction, location of the array on the roof and characteristics of the wind.

144 Introduction of Tip Vane Augmenters onto a Horizontal Axis Wind Turbine.

A wind turbine needs to be designed carefully to extract the energy from an incoming wind stream in an economic manner. The application of tip vane augmenters to a 2m diameter scale model turbine was investigated. High levels of drag masked net power improvements. Identifying the sources of drag, an improved arrangement was developed, tip vanes being mounted on power blades designed to match the augmented air flows. For a combination of tip vane and

blade settings, performance curves were established. Levels of performance were improved over the earlier arrangement and a marginal improvement was demonstrated over the performance of the new power rotor run alone. General performance however, is less than may be expected from an unaugmented rotor.

- 149 Optimal Use of Wind and Diesel Generation On a Remote Scottish Island.

This paper describes the operational experience with a 50 KW wind turbine generator and associated equipment commissioned on Fair Isle in June 1982. Although not designed to operate in parallel with existing diesel generators the control system is such as to optimise, as far as practicable, the use of both means of generation. The wind turbine generator was the first unit to be operated on a commercial basis in the U.K.

European Wind Energy Conference Proceedings Hamburg, F.R.Germany, 22-26 Oct 1984, 681-684 (4p).

- 150 Optimization of the Performance of the Variable Pitch Vertical Axis Wind Turbine.

The optimized performance of a two-dimensional variable pitch Vertical Axis Wind Turbine (VAWT) is investigated using two different theoretical models, the multiple streamtube model and a vortex model. The influence of tip speed ratio, solidity and Reynolds number on the optimal pitch variation is calculated and the corresponding performance curves are produced. Comparison is made with the results of the VAWT without pitch variation and with sinusoidal pitch variation at different amplitudes.

155 Report from WTS - 3 Maglarp, One Year of Operation.

The wind turbine WTS - 3 at Maglarp has been in continuous operation since the acceptance on September 22, 1983. The unit has been operated by the utility company SYDKRAFT as a conventional power plant unmanned and under remote control. The experiences of first year of operation are good. The wind turbine shows good availability power performance and the cost of operation and maintenance is reasonable considering it is a prototype and first generation of large scale WECS. The environmental impacts are causing problems in two areas- TV interference and Acoustic noise.

157 Research and Development for Shrouded Wind Turbines.

In order to exploit the wind power as economically as possible, it was suggested that the wind turbine should be enclosed inside a specially designed shroud. It is shown that up to 80% improvement in the shroud power augmentation can be obtained by the use of an appropriate ring-shaped flap while proper bleeding of the shroud's external flow into its inner rear part will increase its power augmentation by about 25%. Based on the research with shrouds, a pilot plant producing 1 hp at 5m/s with a 3m diameter turbine was built. Its preliminary test results are also included in the review.

162 Transient and Steady State Modelling of a Coupled WECS.

The paper presents a method for simulation of a wind turbine using a DC motor. To verify the method of simulation an American multiblade wind turbine is chosen, loaded by coupling to a centrifugal pump. Using the principle of conservation of energy and characteristics of both constituent units two mathematical models are proposed, one for steady state operation and another for transient state. The close comparison between the theoretical and experimental results

validates the proposed models and the method of simulation.

Wind Enng 9,3;1985;180-199(20p)

165 What is the Most Economical Size for a Large Wind Power Plant?

The question of the most economical size for a large wind energy converter designed to feed the power into a large utility grid and therefore without limitation of the output with respect to the consumer, is an issue of controversial debates. In analysing the problems, facts as production status, assembly and erection costs, O&M costs, and energy production with increasing size are considered. It is concluded that the most economical size for a large WEC strongly depends on the numbers produced and operated. For the nearest future - with the expectation that only small numbers of larger WECs come to a commercial application - the economical size of a rotor diameter seem to be in the range of 50-60m.

European Wind Energy Conference Proceedings Hamburg, F.R. Germany, 22-24 Oct 1984, 730-734(5p)

167 Wind Energy Conversion Systems..

The successful harnessing of wind power source depends on two main factors, the first one is to have a detailed and extensive wind measurement programme at national level, and secondly to either develop or select Wind Energy Conversion Systems (WECS) to match the local wind regimes. The selection of WECS developed in one country may not be the best suited for another. Due consideration to the local conditions should be given. Finally, the greater acceptance of WECS for various applications would depend on producing WECS which are fool proof and that could survive the severest of weather conditions to which WECS are often subjected too.

Int J Solar Energy 3,2; 1985; 43-71 (29p).

169 Wind Energy for Pumping Irrigation Water.

Wind power alone normally has difficulty in supplying all the energy needed for irrigation during these peak water-use periods. However, with wind-assist pumping systems, sufficient water is supplied and electrical energy or diesel fuel is saved. Electrical wind-assist pumping systems provide sufficient energy for irrigation pumps of the same size with excess energy available in all months except July & August. Wind diesel pumping systems reduce fuel consumption by 30 percent when used from March through October.

Clark, Nolan R

170 Wind Power Potential of Saudi Arabia.

Wind data for 20 locations in Saudi Arabia have been analysed. Monthly and annual mean wind speeds and wind powers have been determined. The latter range from 2.5 to 4.4 m/s and from 21.8 to 77.7Wm⁻² respectively. Specific outputs from two hypothetical aerogenerators with rated wind speeds of 5 and 7m/s have been estimated. Examples of monthly mean wind speed and wind power temporal variations are given. Results suggest that wind power would be more profitably used for local and small-scale applications.

European Wind Energy Conference Proceedings Hamburg, F.R. Germany, 22-26 Oct 1984, 226-230(5p)

174 Windmill Tip-Speed Ratio Regulation Using an Impedance-Matching Control System.

A discussion of the approaches to, and benefits of windmill tip-speed ratio (TSR) control is presented. Rotational speed regulation via load-controlled impedance matching is identified as the most efficient control method. An all-mechanical, self-powered windmill TSR controller using this method is presented with a discussion of its operation and wind tunnel test results. A design methodology is presented and used to design a controller for a windmill driving an electrical generator and for the same windmill driving a water pump. These designs are verified with a digital computer simulation using real wind data. The simulation results also demonstrate the economic feasibility of the system.

175 Cooling for Vertical Heat-Generating Channels in Steam-Water Counterflows.

Experimental research was conducted on a heat emission crisis when water is boiling in vertical tubes with one closed end. This crisis is the result of a hydrodynamic crisis ("flooding") of steam-water counter flows, which leads to a reduction in the flow rate of the downward flowing water in the channel. An equation is given for determining the time interval between the moment that flooding starts until the moment that the surface temperature of the heat-generating channel begins to rise. A calculated function for determining the critical thermal flux is given and compared with experimental data.

178 Influence of Long-Term Steam-Turbine Operation on the Properties of Rotor and Casting-Part Material.

The mechanical properties and heat-resistance characteristics of the metal in standard rotors and cast casing parts were determined after various periods of operation (22,000-198,000 hours). The stability of the service properties of R2 and R2MA rotor steels and 15Kh1M1FL casing steel during long-term steam-turbine operation was determined. The sum total of the data obtained during research on rotor and casing-part metal after long-term operation show that these steels have sufficient service-property stability. Therefore, steam turbines can be operated beyond their calculated service life.

179 On -line Optimal Dispatch: A Knowledge-Based Approach.

This paper presents a new method for the on-line optimal dispatch of real and reactive power generations. Rather than using standard iterative algorithms, the approach is based on recognizing similarities with previously studied situations and on using similar samples to linearly predict the optimal generator settings. This approach greatly simplifies the on-line computational burden. For practical applications the differences between the predicted and optimal values are quite acceptable. Large errors can be avoided by controlling the degree of similarity with the base samples.

Int. J. Energy Systems 5,3;1985;95-99 (5p)

- 80 Application of the Expenditure Function in Electricity Pricing:
Optimal Residential Time-of-Use Rate Option.

This paper derives the optimal electricity prices when a customer can choose between paying the TOU rates and full incremental costs of a TOU meter and remaining on a flat rate schedule. In the model described consumer surplus is seen as the difference of two expenditures evaluated at the original flat rate and the new rate schedule (which may be flat or TOU) chosen by a customer according to a self-selection rule. The following section solves the optimization problem and presents the optimal pricing rules. It restates these rules with the help of measures of customer price responsiveness. The concluding section summarizes major findings and discusses the validity of this analysis in the context of the residential market in Northern California.

The Energy Journal 6,2; April 1985;25-39(15p)

188 Future Direction for Load Management.

It has been concluded that although load management programs have been successful in reducing peak electrical demand, future program must be designed to: 1) fill valleys as well as shave peaks and 2) give customers more choice about the way they consume energy. With the operation of the Diablo Canyon and the Helms Power Projects, PG and E's projected generation capabilities will increase by approximately 3000MW. In the near future, not only will the threat of summer brownouts and blackouts be sharply reduced, but at times base-load capacity may exceed demand. Given these changes, load management strategies should be modified to induce customers to buy more off-peak energy.

197 Short-and Long-run Marginal Cost Pricing: On their alleged equivalence.

The equivalence between short-run marginal cost (SRMC) and long-run marginal cost (LRMC) is valid only under the restrictive assumption that the capacity can be varied continuously. This means that indivisibilities, irreversibilities and durability of investments are ignored. Where such phenomena exist, as in electricity production and distribution, pricing according to LRMC is neither theoretically valid nor applicable. It is not surprising that it has been difficult for public utilities to define the LRMC concept operationally; average cost concepts are used as 'approximations.' Under these circumstances it is advisable to dispense with the LRMC concept altogether and rely on pricing based on SRMC.

198 Statistically Adjusted Engineering (SAE) Models of End-Use Load Curves.

Models that combine engineering and statistical approaches to estimating customer-specific end-use load curves are developed and demonstrated. Simulated end-use loads from engineering methods enter as explanatory variables in statistical models and estimated parameters adjust the engineering loads on the basis of customers' observed loads. The resulting end-use loads, called statistically adjusted engineering (SAE) loads, depend on a variety of conditioning variables, including weather and the size and type of the customer's dwelling and income and other characteristics of the household. Using data from a Los Angeles sample of households, several SAE models are estimated that differ in the flexibility that allow in the adjustment of the engineering loads.

200 Trade-Offs for Conflicting Social Objectives in the Extraction of Finite Energy Sources.

Three social objectives figure prominently in the extraction of finite energy resources, namely income maximization, environmental quality and inter-generational concern. Owing to lack of complementarity, the pursuit of these objectives often result in conflicts. As a result, extraction strategies should be based on the determination of trade-offs between the objectives. The paper deals with the formulation and illustration of a systems model to determine these trade-offs. The recognition of such trade-offs results in a greater conservation of the finite energy resource, and hence could act as an incentive for the development of alternative energy sources.

201 Use Management Accounting to Plan and Control Your Energy Program.

Explores the problems of current energy management techniques and outlines a planning and control method, based on costs, to correct them. It is concluded that energy consumption should be viewed as a cost of doing business and should be accounted for as such. With this energy cost perspective, an effective formal energy management system and a universally comparable performance reporting system can be developed. With this management approach, energy will receive the economic attention it requires.

Strategic Planning and Energy Management 5,1;1985;16-26(11p)

202 Using Cost of Electric Service Interruption Surveys in the Determination of a Composite Customer Damage Function.

This paper presents summary results of a recent Canadian cost-of-interruption mail survey of residential, commercial (retail), small industrial and large user customer sectors. The variation of cost among the subgroups within the sectors is outlined. These cost-of-interruption results, together with findings of other studies are used to explore the concept of creating a composite cost-of-interruption function for a particular service area with a known customer mix. The application of such a customer damage function and its inherent strengths and weaknesses are discussed.

Fuel Cells

203 Fuel cells.

Reviews the applicability of acid electrolyte fuel-cell systems towards power generation for operating electric vehicles. The progress that has been made in the catalysis of methanol oxidation and oxygen reduction has been reviewed with emphasis on methanol electrode and those aspects of the air electrode of particular relevance to methanol-air fuel cells. The applicability of alkaline fuel cells as power sources for electric vehicles is reviewed. The electrochemical and material science aspects have been covered because the electrochemical cell is the heart of the fuel cell and determines the technical feasibility of such power plants.

204 High-Temperature Fuel Cells for Power Generation.

An analytical model of high-temperature solid-electrolyte fuel cell (HTSEFC) performance is described. The resulting numerical model yields a detailed description of the electric potential distribution along the air and fuel electrodes of the HTSEFC. This information is used to determine overall HTSEFC operating performance as well as the various overvoltages which detract from such performance. The model yields results that compare favorably with the published experimental data from Westinghouse.

205 Impedance Measurements of Air-Oxidized and H₂ Annealed Raney-Ni Catalysts for Alkaline Fuel Cells.

The kinetic reactions at the three-phase boundary (electrolyte/catalyst/gas) is investigated by measurements of n-1 characteristics and exchange current densities. In addition, impedance measurements were used to get further information on the oxidation kinetics of H₂ in H₂ electrodes of alkaline H₂-O₂ fuel cells.

32 ENERGY CONSERVATION

206 Study of the Operating Characteristics of a Water-Lithium Bromide Absorption Heat Pump.

Performance data have been obtained on an experimental water-lithium absorption heat pump constructed largely from standard glass components for three concentrators of lithium bromide. The experiments which were carried out for a delivery temperature of 70 C show that the co-efficient of performance decreases and the temperature lift increases with an increase in flow ratio and an increase in the concentration of lithium bromide. Coefficient of performance between 80 and 90 percent of the theoretical maximum possible values were obtained.

207 Study of the Thermal Characteristics and Potential for Energy Conservation at Four London Office Buildings.

Four office buildings have been selected to represent typical constructions over the last half century. Each has been simulated by the THERM computer program and accuracy of the models checked against actual fuel bills. By altering the computer models of the four buildings it has been possible to investigate various means of reducing energy consumption.
